

# TOWARD EFFECTIVE ALZHEIMER'S THERAPY: PROGRESS AND COLLABORATION

Paul S. Aisen, MD  
Department of Neurosciences  
University of California, San Diego

# Brief History of AD Therapeutics

- 1906: Dr. Alois Alzheimer describes AD
- 1906-1970's: General assumption that this is an unusual and untreatable degenerative disease of middle age
- 1976: Dr. Robert Katzman editorial: The Prevalence and Malignancy of Alzheimer's Disease
- Late 1970's Cholinergic hypothesis suggests treatment possibilities
- 1984 Drs. Glenner and Wong purify and characterize brain amyloid
- 1985: First positive treatment study in AD
- 1993: Tacrine is approved; 3 other similar drugs follow
- PS1, PS2, APP and ADAD
- 2003: Memantine is approved, representing a second therapeutic class for AD
- And then a lost decade? What went wrong?

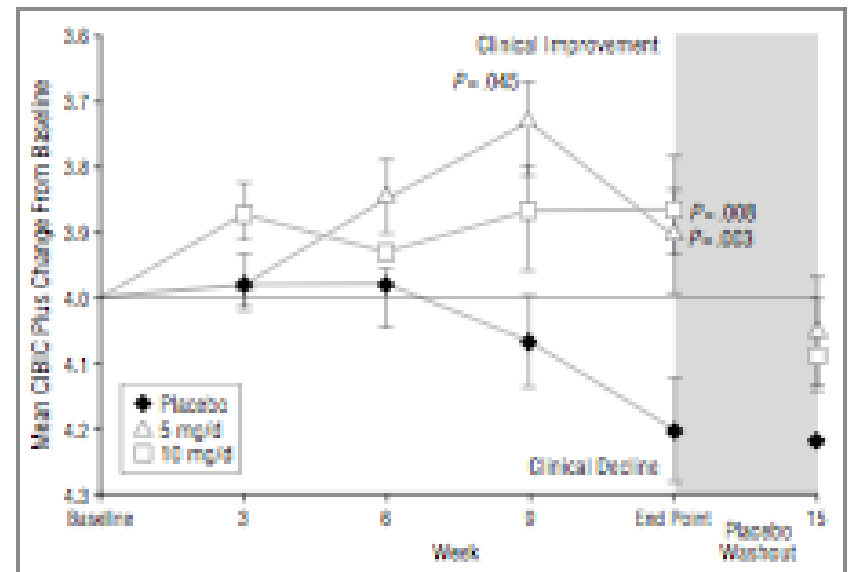

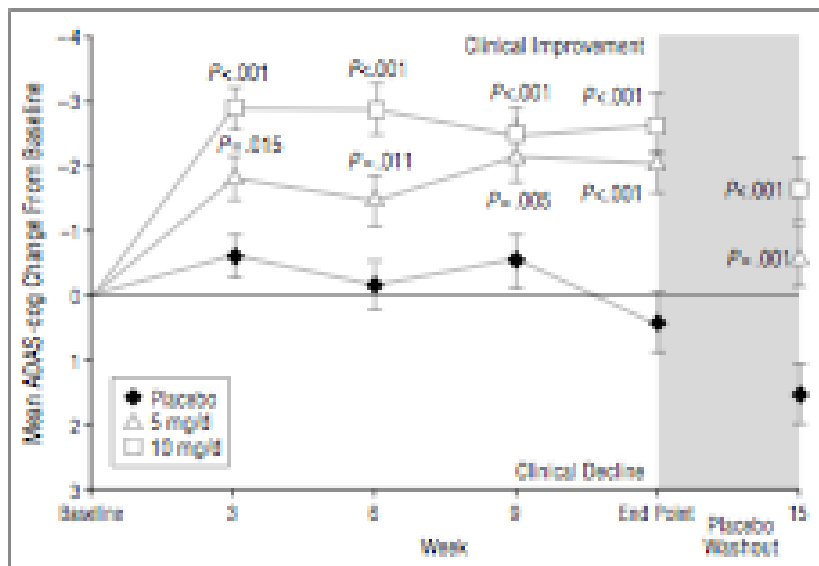

# FDA Guidelines for AD Trials

- Co-Primary outcome measures
- Memory/cognition test, plus global or functional measure to establish clinical relevance
- ADAS-cog has worked well for cognitive enhancers in mild-moderate AD
- CIBIC-plus (CGIC) has worked well as a global
- CDR-SB, ADCS-ADL, DAD reasonable co-primaries for long trials

# ADAScog change, CIBIC+ for assessment of cognitive enhancement

## 12 Week Phase II Donepezil Trial

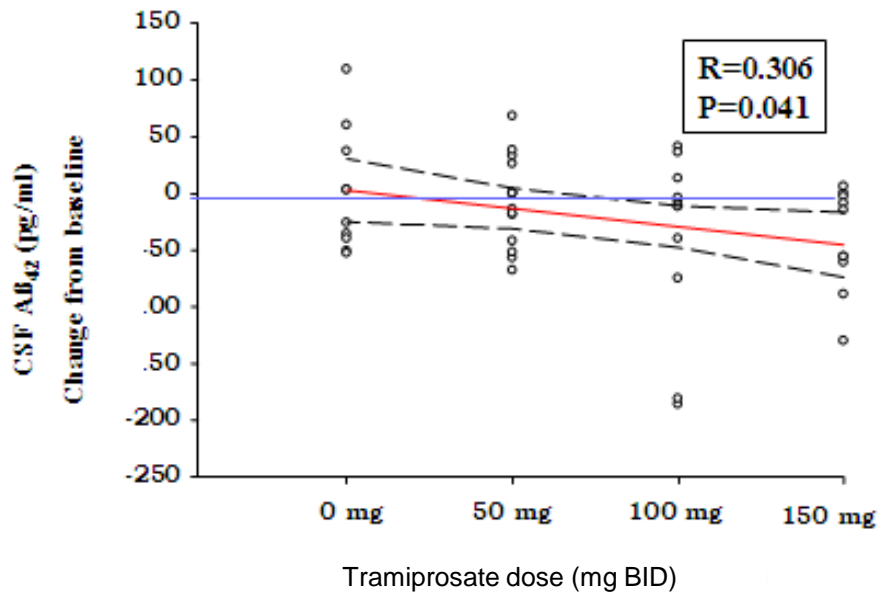

# Disease-Modifying Drug Development: Phase II/III problems

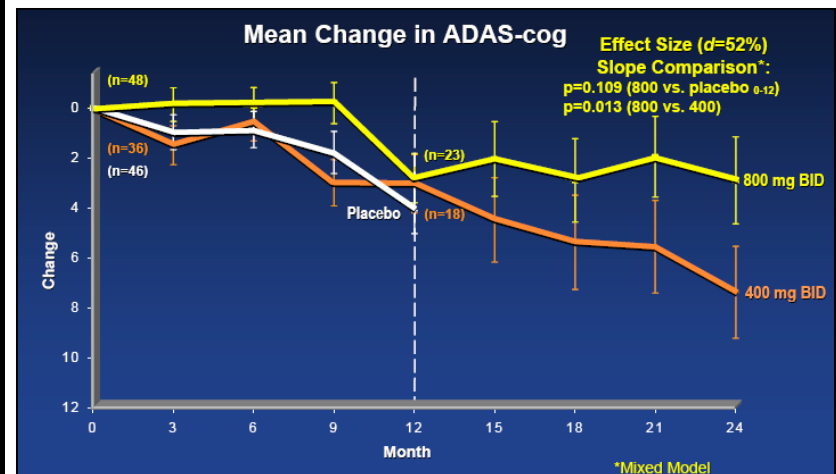

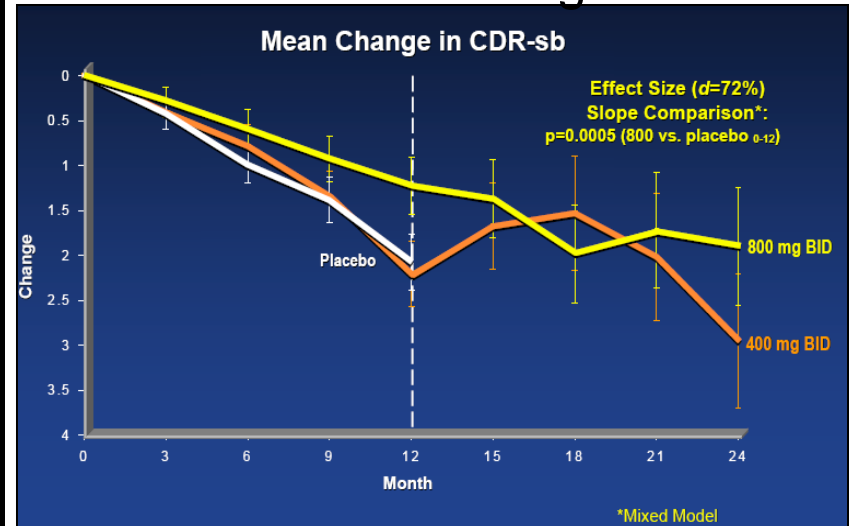

- No short-term benefit expected, rather change in slope of decline
- Placebo groups in mild AD studies don't decline in 6 months; placebo decline minimal in 12 months
- To see effect on slope, need hundreds or thousands of subjects followed for 18 months
  
- Cannot see proof of efficacy in Phase II-type trial (in contrast to currently approved drugs)
- So we have lost a critical piece of the drug development process: the Phase II study

# Comparison between Tramiprosate and Tarenflurbil Phase II trials

## Tramiprosate: CSF-A $\beta$ Results

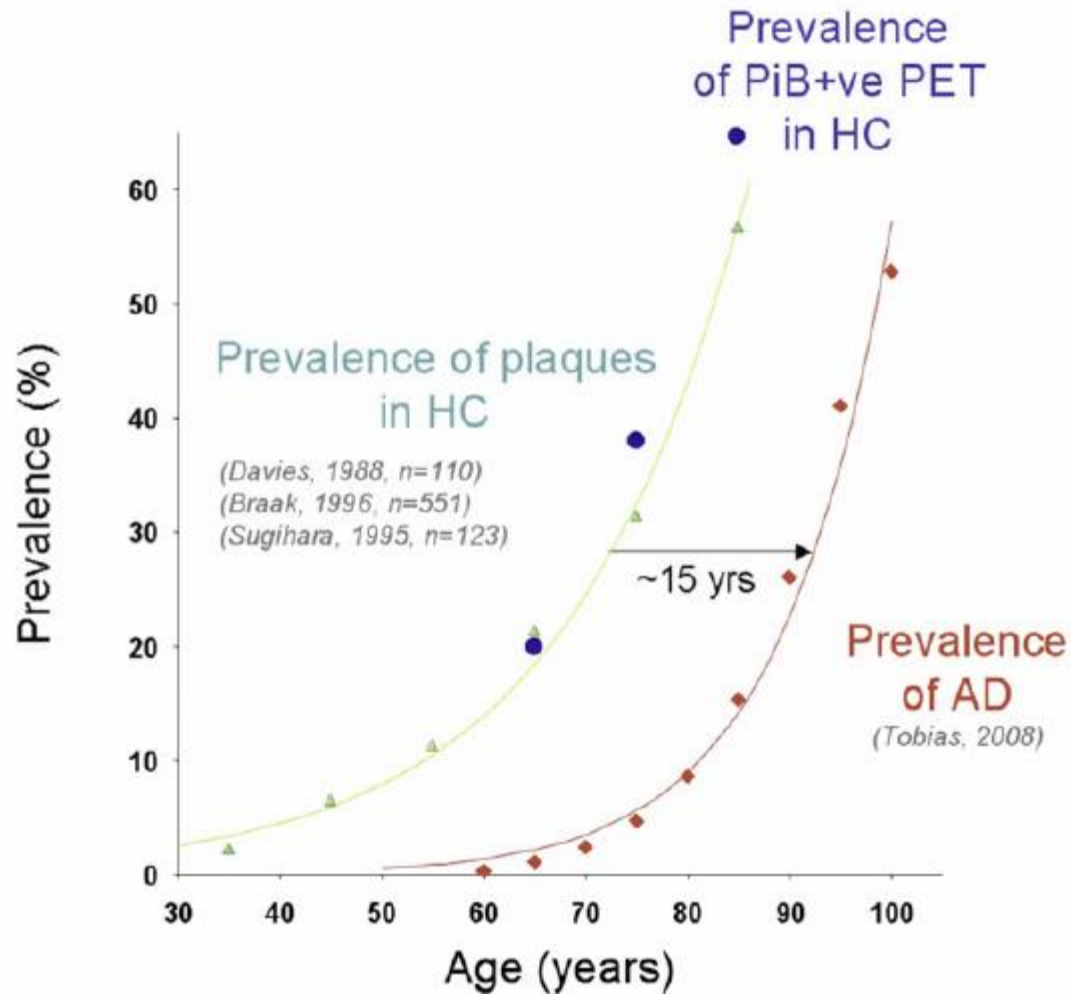

## Tarenflurbil: Clinical/Cognitive Results

- 
- Even more important than the methodologic challenges, it is very plausible that the dementia stage of AD may be too late for disease-modification
  - Especially for targeting amyloid

# AIBL: Amyloid deposition by PIB and by autopsy precedes AD dementia by 15 years

# MCI Trials

- FDA, EMA never accepted MCI as a treatable entity for drug development
- Therefore, pre-dementia trials had to use time-to-dementia (a treatable entity) as outcome
- But MCI trials have not been successful

# Issues with prior MCI trials

- Subject selection
- Variable conversion rate
- Subjective endpoint
- Artificiality of distinction between MCI and mild AD

## Perspective

# Regulatory Innovation and Drug Development for Early-Stage Alzheimer's Disease

Nicholas Kozauer, M.D., and Russell Katz, M.D.

N Engl J Med 2013; 368:1169-1171 | [March 28, 2013](#) | DOI: 10.1056/NEJMp1302513

# Kozauer and Katz, NEJM, 2013

- A specific suggestion ... for trials focusing on patients in whom overt dementia seems imminent is the use of a single scale that combines assessment of both cognition and function, such as the score on the Clinical Dementia Rating Sum of Boxes (CDR-SB).
- For patients whose disease is at an even earlier clinical stage, so that functional impairment would be more difficult to assess, it might be feasible to approve a drug through the FDA's accelerated approval pathway on the basis of assessment of cognitive outcome alone.

# Better pre-dementia designs

- Now that FDA and EMA seem amenable to the idea of pre-dementia AD (eg, by Dubois criteria) we can abandon time-to-dementia design
- Operationalize Dubois criteria (eg MCI plus low CSF abeta42)
- Primary outcome: continuous measure such as CDR-SB (to capture effect on primary manifestations of disease and establish clinical relevance)
- Much more powerful than traditional MCI trial design

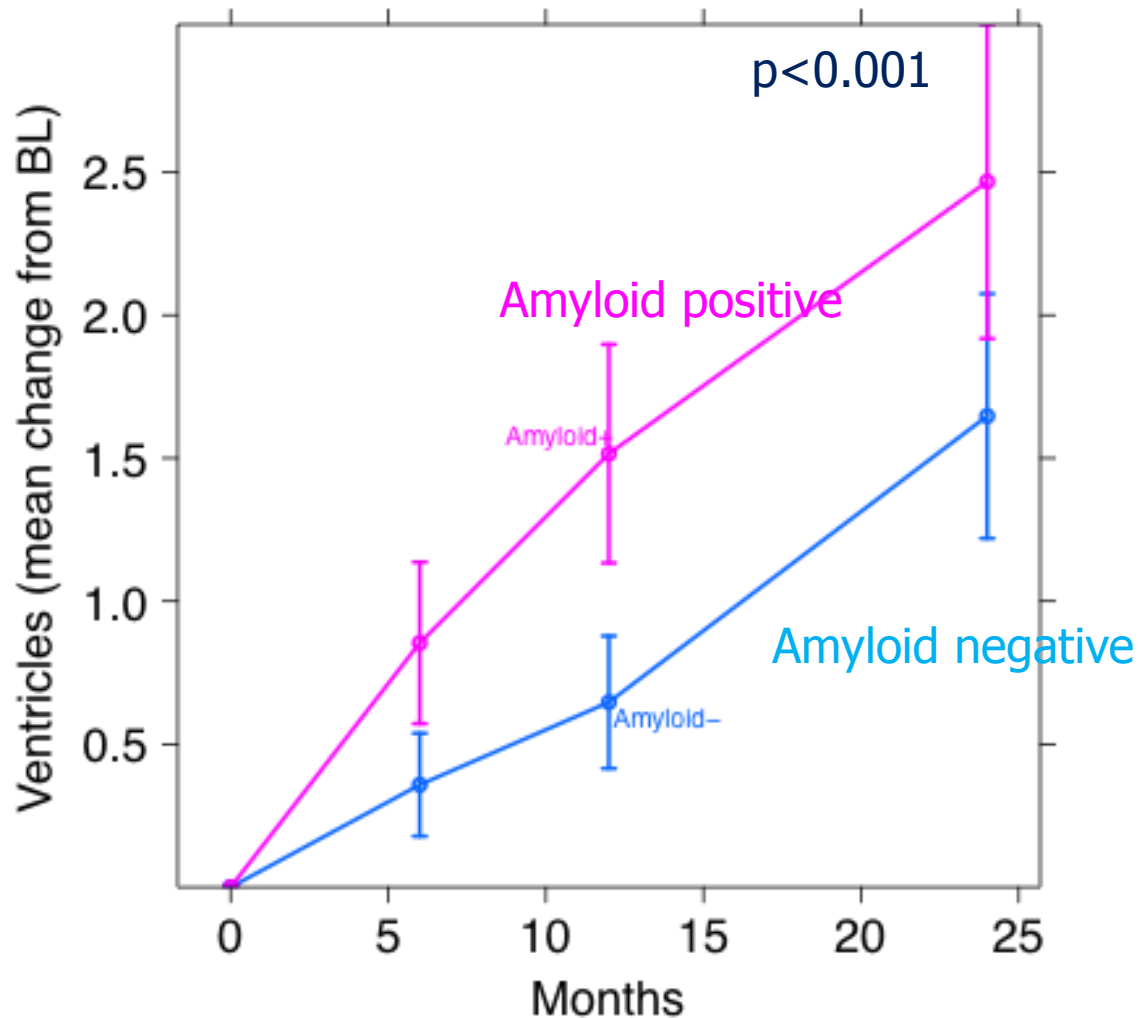

- So we have moved from successful symptomatic and unsuccessful disease-modifying drug trials in AD dementia to pre-dementia (prodromal) AD as a population for studies
  - ▣ Likelihood of success must be significantly greater
- Next: preclinical AD
- (And someday: primary prevention)

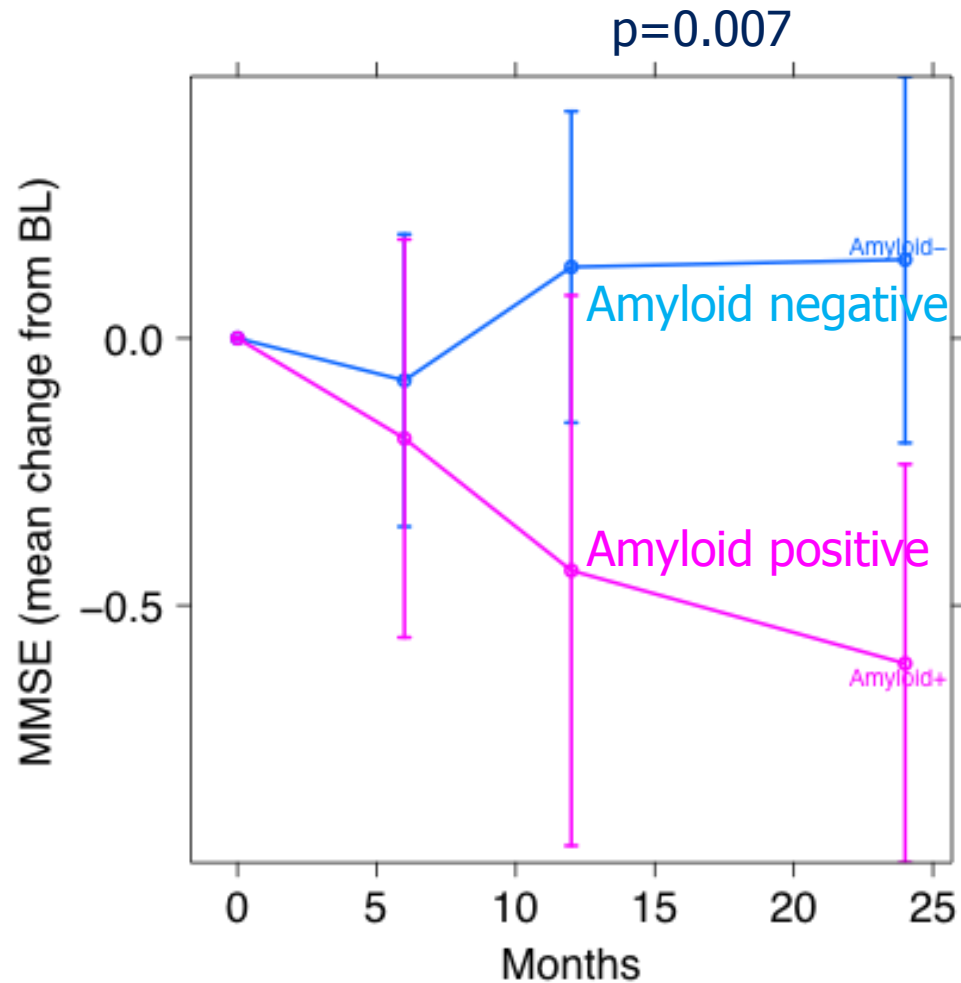

# Preclinical AD?

- One third of the ADNI normal control group (CDR=0) are amyloid positive by CSF or PET
- Is this “preclinical AD”?

# Ventricular volume change in normals is linked to amyloid

# MMSE change in normals is linked to amyloid

Fig 1. (A) Estimated evolution of the mean Isaacs Set Test (IST) score (and 95% confidence interval [CI]) during the 14 years preceding the diagnosis of Alzheimer's disease (AD; red curve for future AD subjects; blue curve for healthy control subjects; scores ranging from 0–40). (B) Estimated evolution of the mean Wechsler Similarities test (WST) score (and 95% CI) during the 14 years preceding the diagnosis of AD (red curve for future AD subjects; blue curve for healthy control subjects; scores ranging from 0–10). (C) Estimated evolution of the mean Mini-Mental State Examination (MMSE) score (and 95% CI) during the 14 years preceding the diagnosis of AD (red curve for future AD subjects; blue curve for healthy control subjects; scores ranging from 0–30). (D) Estimated evolution of the mean Benton Visual Retention Test (BVRT) score (and 95% CI) during the 14 years preceding the diagnosis of AD (red curve for future AD subjects; blue curve for healthy control subjects; scores ranging from 0–15).

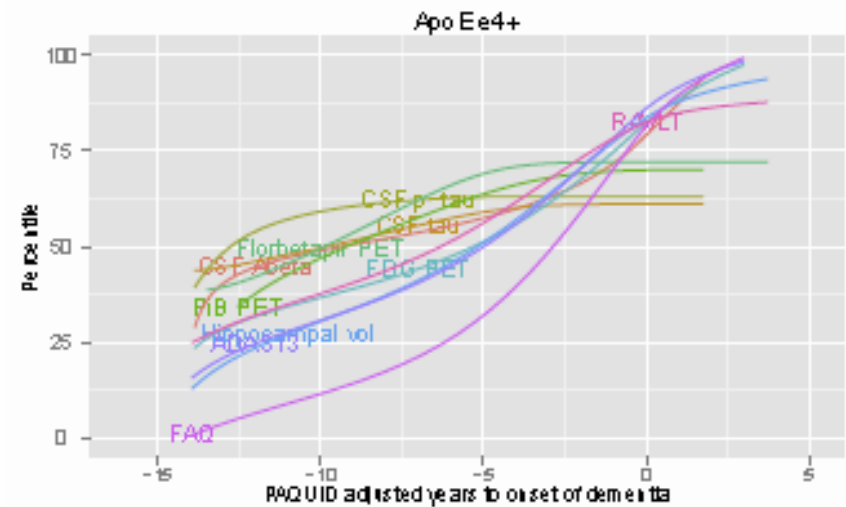

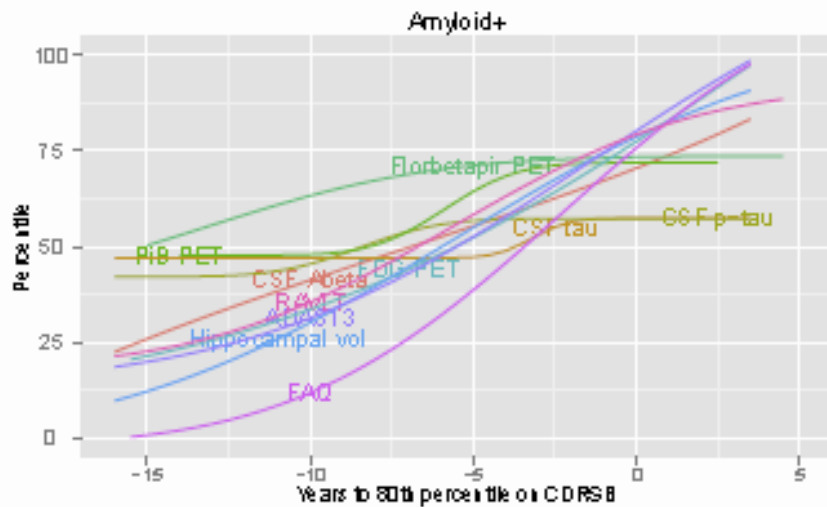

Figure 1: Dynamic biomarkers of the AD cascade hypothesized by Jack et al. [4]

Estimating long-term multivariate progression from short-term data. Donohue et al, Alzheimer's and Dementia, 2013:

Cognitive change occurs as early as functional/structural biomarker change

Amyloid+

ApoE e4+

# Secondary prevention (very early treatment of AD)

---

target amyloid-related cognitive decline in clinically normal older individuals

# ADCS A4 Trial Design (Sperling, Aisen)

## Anti-Amyloid treatment in Asymptomatic AD

- Screen clinically/cognitively normal 65+ year-olds
- Select those with amyloid in brain by PET
- Enroll in a 3 year RCT of an anti-amyloid rx (solanezumab)
- Primary outcome: cognitive composite
- Broad secondaries including computerized cognitive composite, PRO, functional/structural MR, CSF

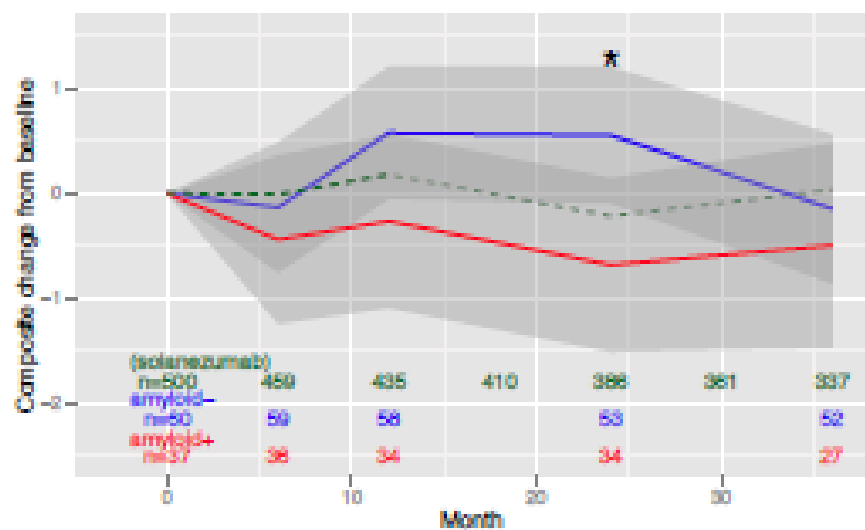

# ADCS-PACC

- Based on review of the literature from cohort studies data from “normal controls” who progressed to MCI or AD dementia, a composite measure sensitive to change in preclinical AD would likely require assessment of these key domains:
  - episodic memory
  - executive function
  - orientation

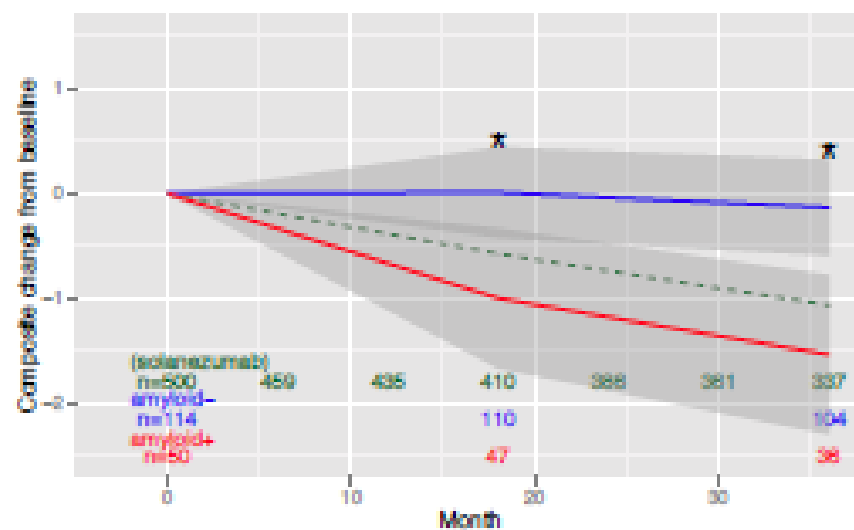

# The ADCS-PACC includes:

- Free and Cued Selective Reminding Test (FCSRT)
- Delayed Paragraph Recall
- Digit-Symbol Substitution test
- MMSE
  
- Sum of z scores

### ADNI by A $\beta$

### AIBL by A $\beta$

### ADCS PI by CDR-G Progressor

### ADCS PI by ApoE- $\epsilon$ 4

# Cognition is the best biomarker for AD trials

- Face validity
- Moves in the expected direction (in contrast to volumetric MR)
- Links early, middle and late stage disease-  
best for registration
- *Feasible primary outcome measure at the earliest identifiable stage of AD*

# How will we get to primary prevention?

- Clarify the transition from normal aging to AD
- Identify those nearing that transition (epidemiology, genetics)
- Demonstrate impact of therapeutics on the transition
  
- Establish mid-life primary prevention

# PET scanning will be the new colonoscopy

- Or LPs ...
- Or plasma abeta may be the new cholesterol (once we figure out how to measure and analyze plasma abeta)

# (Somewhat) controversial statement

- The amyloid therapeutic hypothesis is alive and well
- (Despite dozens of negative trials)
- The focus of trials on amyloid is appropriate
- (Even as we must continue to test other targets)
- We will get this right

# Other therapeutic approaches

- Tau immunotherapies
- Glucose/insulin
- NGF, BDNF, exercise
- Anit-inflammatories? Target complement?
- APOE-related therapeutics
- Clues from new genes?

# Justification for optimism

- So many brilliant basic and clinical scientists
  - ▣ We have very promising therapeutic candidates now, plus better trial designs
  
- So many, many generous volunteers in our trials

# Justification for optimism: beyond the science and the trials

- Standardization and data sharing (M Weiner)
- Collaboration (M Carillo, Mike Weiner for WW-ADNI; B Vellas, J Touchon)
- National/international harmonization and vision (M Carillo, G Vradenberg, Z Khachaturian, N Buckholz)
- Regulatory vision (R Katz, C Sampaio)
- National leadership (R Petersen)
- Academic industry partnerships (DIAN, API, A4 ...)

# Conclusions:

## Lessons for AD trial design

- AD is a gradually progressive disorder lasting many years; MCI and AD dementia are artificial, fuzzy constructs, useful clinically but counter-productive in trials
- In prodromal AD, assessing treatment effects on continuous measures (eg CDR-SB) is much more powerful than time-to-dementia or other time-to-event designs
- Biomarkers are powerful but tricky
- Cognition may be the best biomarker (despite measurement challenges)

# Conclusions: Lessons for AD trial design (continued)

- Probably wise to treat as early as possible
- Very early treatment trials, ie, secondary prevention trials targeting amyloid-mediated decline, are now feasible (with clear regulatory guidance)
- Primary prevention is the ultimate goal but we need more study of the transition between normal and preclinical AD (ADNI3?)

# Final words

---

- *We will get there*
